

# South of the crater

## South of the crater

- Drill hole 94 has ~10 vol% impact melt and ~1.45 vol% lechatelierite present within the first 2 m.
- Only minor to trace amounts of impact melt and lechatelierite are present below 2 m depth in 94, and throughout drill hole 95.
- Substantial amounts of mixing between all target rock lithologies are found in both drill holes 94 and 95.
- This transect sheds light onto some internal structures and complexities of the Meteor Crater ejecta blanket.
